"Changes in Blood Picture Caused by Hypoxia and Low Pressures."

Bratislava, Biologia, Vol 21, No 7, 1966, pp 503 - 511

Abstract: Adaptation changes in the blood system of an organism traumatized by various kinds of low pressures and hypoxia were studied in experiments on guinea pigs. Experiments lasted for 80 seconds, 28 minutes, 7 hours, and 1, 6, 12, 18, and 24 days. Extensive changes in the blood picture were found; these depend on the lowering of the pressure, available oxygen, and duration of the experiment. The increase in erythrocytes and in hemoglobin is most pronounced after 7 hours of exposure to low pressures. 4 Figures, 5 Tables, 4 Western, 7 Czech, 2 Russian, 2 Rumanian, 2 East German references. Title : The Change in the Course of Arthus Phenomenon and in Precipitins' Titer During Drug Induced Sleep.

Orig Pub : Bratisl. lekar. listy, 1956, 1, No 9, 513-523.

Abstract : The rabbits' light sleep that had been induced by urethan and medinal failed to change the course of Arthus phenomenon (AP) or the titer of precipitins (TP). Deep sleep was accompanied by depressed AP and a lowered TP for 3 days. When a toxic dosage of hypnotics was given no depression of AP and TP was observed.

A cortical dynamic stereotype was elaborated in rabbits actively immunized with pig serum containing lipid adjuvants. The animals were given repeated injections of physiological saline under standard conditions. In some series of experiments it was not possible to influence the development of the Arthus phenomenon when pig serum was given as antigen instead of saline. A direct relationship between the severity of the skin lesions in the Arthus phenomenon and the titre of specific precipitating antibodies was confirmed, in agreement with data in the medical literature.

2849. EXPERIMENTAL PULMONARY EMBOLISM CAUSED BY AMNIOTIC FLUID OR MECONIUM - Experimentálna pl'úcna embólia plodovou vodou, resp. smolkou - Brozman M. Ust. Patol. Anat. Lek. Fak., Univ. Komenského, Bratislava - BRATISL. LEK. LISTY 1958, 38(II)/8 (444-456) Tables 1 illus. 6

This study revealed that individual components of amniotic fluid or meconium such

as mucus, cornified epithelia and lanugo are gradually discarded from the lungs. An important finding was the presence of coarse granular masses, staining dirty-grey with Van Gieson's picrofuchsin in frozen sections in the lumina of many pulmonary vessels. By perfusion of the heart-lung preparations with meconium, the author proved that these masses are not a component of the amniotic fluid or meconium, as was formerly supposed, but that they are probably formed by agglutination of thrombocytes. These thrombocytic thrombi were abundant in early deaths in shock, but no longer could be found when the rabbits were sacrificed after several hours or days. In these instances many polymorphonuclear leucocytes filled the pulmonary vessels. In many rabbits no clearly positive fibrin clots could be demonstrated in the pulmonary blood vessels, while in others they could be found, but in a relatively small quantity.

Prague, Časopis Lékaru Ceských, Vol CII, No 32/33, 16 August 1963, pp 660-664.

Abstract [Author's English summary]: using the method of fluorescent antibodies the author identified platelets as well as fibrinogen and serum proteins in organs of experimental animals in which thrombotic processes were produced by thromboplastin or thrombin, and in animals with embolic processes induced by amniotic fluid or meconium suspension. Simultaneous thrombotic processes developed in the animals to a different extent. The experiment confirmed the existence of antigens common in platelets and fibrinogen not always taken into account when identifying the structure difficult to identify by histological methods. Discussed is the application of the method in investigating thrombotic processes, atherosclerosis, and some other diseases. Forty references, including 3 Czech and 2 Slovak.

TITLE: Changes caused in bacterial cells by ultraviolet radiation

SOURCE: Biologia, no. 8, 1965, 632-639

TOPIC TAGS: UV irradiation, radiation biologic effect, bacteria, nucleic acid, x ray irradiation, biosynthesis, enzyme

ABSTRACT: Changes caused by ultraviolet radiation leading to the interruption of the development of the cultures and all divisions are discussed. The radiation is absorbed mostly by nucleic acids, the most effective radiation is in the 220-300 mμ wavelength range. The radiation has a substantially lower energy content than X-ray radiation; its effect is based on the fact that it induces certain chemical reactions; the photo-products produced are mainly compounds resulting from alterations of pyrimidine bases; purine bases are much less sensitive. The formation of thiamine dimers is the most serious biological consequence of ultraviolet irradiation. Synthesis of nucleic acids and cell divisions are inhibited. Recovery processes after the irradiation are either of the enzymatic or the recombination type. The dark repair reactivation is described. Orig. art. has: 2 figures. 1974

AUTHORS: Kloss, A. and Brožovsky, M.

TITLE: Preparing vacuum seals by the HF heating

PERIODICAL: Referativnyy zhurnal, Avtomatika i radioelektronika,  
no. 1, 1962, abstract 1-3-57 ye (Techn. zprávy CKD,  
1960, 6, no. 10, 299-336)

TEXT: The following requirements are laid down as to the proper-  
ties of vacuum of electrodes seals of welded ignitrons: High elec-  
tric and mechanical strength (especially against vibration), high  
temperature stability within the -50 to +450°C range (the ignition  
welding temperature). Advantages and disadvantages of various types  
of vacuum seals are also considered: Vacuum welded ceramic, vitri-  
fied, glass-metal. It is shown that for ignitrons, metal-ceramic  
seals are the most suitable ones. The following main features of  
metal-to-glass joints are analyzed: The problem of oxidation of  
Kovar and the methods of determining its 'oxidation curve': the  
results of experiments related to the choice of optimum technology  
Card 1/2

Preparing vacuum seals ...

S/194/62/000/001/030/066

of vitrification are given which have shown that using a suspension with glass particles  $\geq 10^{-4}$  mm in diameter, the amount and dimensions of air bubbles in the enamel decrease. A short description of the sealing-in technique by means of heating of the vacuum anode, grid and ignitron inlets is given. Photographs of vacuum seals of various types are given, together with the microstructure of Kovar at various stages of the technological process, 'oxidation curve' of Kovar in comparison with the analogous curve for steel, schematics of the cross-section of the enamel layer at various stages of vitrification and a photograph of the external view of the equipment. 8 references. TITLE: Effect of light on the surface conductivity of germanium with a clean surface

SOURCE: Fizika tverdogo tela, v. 7, no. 9, 1965, 2803-2808

TOPIC TAGS: <sup>21,44,55</sup> germanium <sup>21,44,55</sup> semiconductor, photoconductivity, surface property, absorption edge

ABSTRACT: Previous studies have shown that compensated split specimens of <sup>21</sup>gold-doped germanium display a surface conductivity which considerably exceeds the volume conductivity at low temperatures. The authors describe the changes in conductivity and various other phenomena which take place when this type of surface is illuminated in the region of natural absorption for germanium, in particular the negative photoconductivity which occurs at the natural absorption edge. Curves are given for the change in conduction current under illumination as a function of wavelength, and for the spectral characteristics of photocurrent in specimens with negative photoconductivity. Analysis shows that the change in photoconductivity under illumination is the result of two effects: a positive and a negative effect with different time lags. Illumination of the clean surface of a specimen often resulted in a reduction in cur-

Card 1/2

ACC NR: AP5022727

7

rent through the crystal, i. e. negative photoconductivity, in the spectral region adjacent to the natural absorption edge on the short wave side. Curves are given for this effect in gold- and nickel-doped crystals. Oscillograms taken during illumination by square light pulses show that the nature of relaxation curves is considerably dependent on wavelength. Analysis of curves for negative stationary photoconductivity as a function of illumination intensity for a clean surface and for the same relationship with respect to positive photoconductivity in a specimen with an oxidized surface indicates that transition from negative to positive photoconductivity may take place under strong incident illumination. It was found that the stationary negative photoconductivity is considerably dependent on the surface conductivity. A model is proposed to explain the negative photoconductivity observed in these specimens. This model may also explain the energy position occupied by surface levels. It is pointed out that further research is needed to definitely establish the mechanism responsible for the observed phenomena. The authors thank P. N. Tomchuk and O. V. Snitko for a number of useful discussions. Orig. art. has: 6 figures<sup>44,55</sup>

Zagadnienie gładkości powierzchni i tolerancji średnic przewodniczących (Prace Przem. Inst. Telekom. No. 21), Warszawa, 1957, PWT, 5 pp., 1 fig., 1 tab.

The author draws attention to the fact that concentration on too great a degree as regards dimensional tolerances and surface smoothness of waveguide diameters leads to the fact that the diameter of the waveguide is too small and the surface is too rough.

morska, 1961, v. 11, no. 6, 173-176)

TEXT: Radar equipment, 1961 series, is described which operates at temperatures between  $-25$  and  $+70^{\circ}\text{C}$  (transmitter) and  $-15$  and  $+55^{\circ}\text{C}$  (receiver), withstands continuous and shock vibrations and a roll of up to  $50^{\circ}$ . The system works at  $9320 - 9500$  Mc/s, with a pulse length of  $0.18$   $\mu\text{sec}$  and a repetition frequency of  $50 - 1200$  c/s. The accuracy of the azimuth determination is  $0.9^{\circ}$ . The supply is from a.c. mains,  $110$  V, or d.c.  $110$  V ( $220$  V), voltage variations  $+10\%$ . The equipment is of modular design and the units can be substituted. Technical and operational data, dimensions, weight and a photograph are given. 7 figures. Title : The Volumetric and Polarographic Determination of  
and Stability Studies on N-Nitroso-N-Methylurea.

Orig Pub: Chem Listy, 52, No 5, 909-914 (1958) (in Czech).

Abstract: Two methods have been developed for the quantitative  
determination of N-nitroso-N-methylurea (I), an  
acidimetric method and a polarographic method. When  
the acidimetric method is used, the excess NaOH left  
after the alkaline hydrolysis of I by the equation  
 $\text{CH}_3\text{N}(\text{NO})\text{CONH}_2 + \text{NaOH} \rightarrow \text{CH}_2\text{N}_2 + \text{NaCNO} + 2\text{H}_2\text{O}$  is ti-  
trated. 150-200 mg I is stirred with 25 ml 0.1 N

Abs Jour: Ref Zhur-Khimiya, No 8, 1959, 27143.

Abstract: NaOH until the evolution of diazomethane bubbles ceases, and the solution is titrated with 0.1 N  $H_2SO_4$  in the presence of phenolphthalein; 1 ml of 0.1 N NaOH is equivalent to 10.3086 mg I. The polarographic determination is made in McElvain buffer solution at pH 5 in the presence of 0.5 ml of 0.2% gelatine solution (the decomposition of I does not proceed in weakly acid medium), after hydrogen is bubbled through the solution. The half-wave potential for the reduction of I is found to be -0.98 v, referred to a standard  $Hg_2Cl_2$  [SCE] electrode. The analytical methods used in the investigation of the stability of I under various conditions are described. The error in the acidimetric analysis is from -0.36 to -0.82% and in the polarographic analysis, from -0.89 to +0.84%. -- J. Vanecek

TITLE: Investigation of the ammonium lactate - ion exchange separation process for trace quantities of rare earth metals

SOURCE: Magyar kémiai folyóirat, no. 4, 1966, 152-158

TOPIC TAGS: rare earth metal, trace analysis, chemical separation, ion exchange resin, chemical stability

ABSTRACT: The most important ion-exchange reaction in the separation of rare earth metals on a cationic ion-exchange resin is the formation of a lanthane-rare earth complex ion. At relatively low eluent flow rates the diffusion rate is determined by the Nernst equation. The stability constants of the intermediate and ultimate reaction products determine solely the exchange process in this flow rate range. The formation of the lactate complexes is generally accompanied by a dropwise change in the charge-phase number. Orig. art. has: 10 figures, 12 formulas, and 2 tables.
